Survival Analysis with R

Exercise set 1

Take a look at the built in colon dataset. If you type ?colon it'll ask you if you wanted help on the colon dataset from the survival package, or the colon operator. Click "Chemotherapy for Stage B/C colon cancer", or be specific with ?survival::colon. This dataset has survival and recurrence information on 929 people from a clinical trial on colon cancer chemotherapy. There are two rows per person, indidicated by the event type (etype) variable – etype=1 indicates that row corresponds to death; etype=2 indicates recurrence.

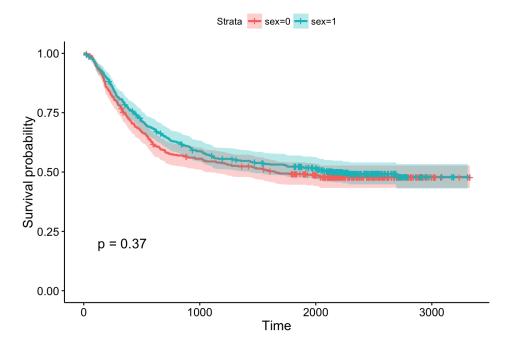

First, let's filter the data to only include the survival data, not the recurrence data. Let's call this new object colondeath. The filter() function is in the **dplyr** library, which you can get by running library(dplyr) or library(tidyverse).

```
library(tidyverse)
colondeath <- filter(colon, etype==1)
head(colondeath)</pre>
```

- 1. Look at the help for ?colon again. How are sex and status coded? How is this different from the lung data?
- 2. Using survfit(Surv(..., ...,)~..., data=colondeath), create a survival curve separately for males versus females. Call the resulting object sfit. Run a summary() on this object, showing time points 0, 500, 1000, 1500, and 2000. Do males or females appear to fair better over this time period?

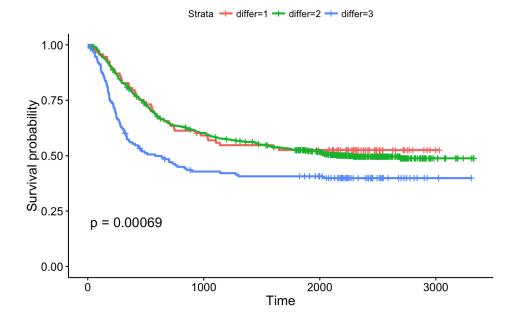

##	sex=0							
##	time	${\tt n.risk}$	${\tt n.event}$	survival	${\tt std.err}$	lower 95%	CI upper	95% CI
##	0	445	0	1.000	0.0000	1.0	00	1.000
##	500	295	146	0.670	0.0224	0.6	27	0.715
##	1000	242	50	0.556	0.0237	0.5	12	0.604
##	1500	222	18	0.515	0.0238	0.4	70	0.564
##	2000	183	12	0.486	0.0239	0.4	42	0.535
##								
##		sex=1						
##	time	${\tt n.risk}$	${\tt n.event}$	${\tt survival}$	${\tt std.err}$	lower 95%	CI upper	95% CI
##	0	484	0	1.000	0.0000	1.0	00	1.000
##	500	338	138	0.713	0.0206	0.6	74	0.754
##	1000	274	59	0.588	0.0226	0.5	45	0.634
##	1500	246	23	0.538	0.0229	0.4	95	0.585
##	2000	211	10	0.516	0.0230	0.4	72	0.563

3. Using the survminer package, plot a Kaplan-Meier curve for this analysis with confidence intervals and showing the p-value. See ?ggsurvplot for help. Is there a significant difference between males and females?

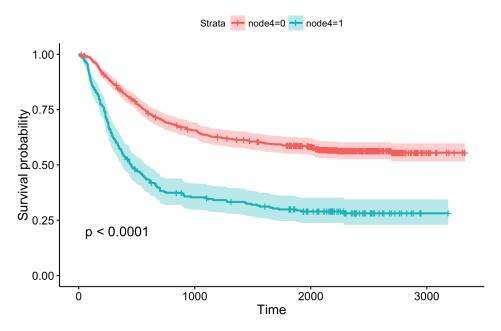

- 4. Create Kaplan-Meier plot stratifying by:
 - a. The extent of differentiation (well, moderate, poor), showing the p-value.
 - b. Whether or not there was detectable cancer in >=4 lymph nodes, showing the p-value and confidence bands.

Survival by tumor differentiation

Survival by involvement in >=4 lymph nodes

Exercise set 2

Let's go back to the colon cancer dataset. Remember, you created a colondeath object in the first exercise that only includes survival, not recurrence data points. See ?colon for more information about this dataset.

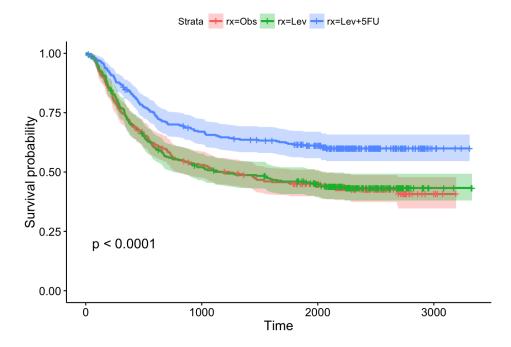

1. Take a look at levels(colondeath\$rs). This tells you that the rx variable is the type of treatment the patient was on, which is either nothing (coded Obs, short for Observation), Levamisole (coded Lev), or Levamisole + 5-fluorouracil (coded Lev+5FU). This is a factor variable coded with these levels, in that order. This means that Obs is treated as the baseline group, and other groups are dummy-coded to represent.

rx	Lev	Lev+5FU
Obs	0	0
Lev	1	0
Lev+5FU	0	1

2. Run a Cox proportional hazards regression model against this rx variable. How do you interpret the result? Which treatment seems to be significantly different from the control (Observation)?

```
## coef exp(coef) se(coef) z p
## rxLev -0.0151 0.9850 0.1071 -0.14 0.89
## rxLev+5FU -0.5121 0.5992 0.1186 -4.32 1.6e-05
##
## Likelihood ratio test=24.3 on 2 df, p=5.17e-06
## n= 929, number of events= 468
```

3. Show the results using a Kaplan-Meier plot, with confidence intervals and the p-value.

4. Fit another Cox regression model accounting for age, sex, and the number of nodes with detectable cancer. Notice the test statistic on the likelihood ratio test becomes much larger, and the overall model becomes more significant. What do you think accounted for this increase in our ability to model survival?

```
coef exp(coef) se(coef)
##
                                                       р

   n= 911, number of events= 456
##
      (18 observations deleted due to missingness)
```

Exercise set 3

The "KIPAN" cohort (in KIPAN.clinical) is the pan-kidney cohort, consisting of KICH (chromaphobe renal cell carcinoma), KIRC (renal clear cell carcinoma), and KIPR (papillary cell carcinoma). The KIPAN.clinical has KICH.clinical, KIRC.clinical, and KIPR.clinical all combined.

1. Using survivalTCGA(), create a new object called clinkid using the KIPAN.clinical cohort. For the columns to extract, get both the disease code and the patient's gender (extract.cols=c("admin.disease_code", "patient.gender")). The first few rows will look like this.

```
times bcr_patient_barcode patient.vital_status admin.disease_code
## 1
      1158
                   TCGA-KL-8323

                                                                      kich
```

```
## 5
      3553
                   TCGA-KL-8327
                                                                        kich
## 6
     3127
                   TCGA-KL-8328
                                                      0
                                                                        kich
     patient.gender
##
## 1
              female
## 2
              female
## 3
              female
## 4
                male
## 5
              female
## 6
                male
```

2. The xtabs() command will produce tables of counts for categorical variables. Here's an example for how to use xtabs() for the built-in colon cancer dataset, which will tell you the number of samples split by sex and by treatment.

xtabs(~rx+sex, data=colon)

```
## rx 0 1
## Obs 298 332
## Lev 266 354
## Lev+5FU 326 282
```

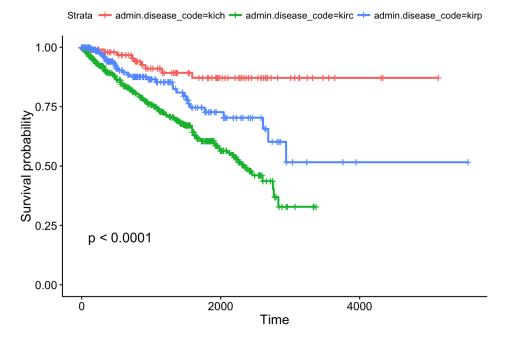

Use the same command to examine how many samples you have for each kidney sample type, separately by sex.

```
## patient.gender
## admin.disease_code female male
## kich 51 61
## kirc 191 346
## kirp 76 212
```

3. Run a Cox PH regression on the cancer type and gender. What's the effect of gender? Is it significant? How does survival differ by each type? Which has the worst prognosis?

```
##
                             coef exp(coef) se(coef)
                                                          z
